

A niche *prediction market* for flight delays.

It works as *parametric insurance*. Settled automatically on-chain. Paid out in *stablecoins*. Prediction markets, pointed at something useful.

THE PROBLEM

Both sides are *broken*.

Travelers don't trust the payouts. Underwriters can't find real yield.

FOR TRAVELERS

Travel insurance is *adversarial*.

Whoever decides if you get paid is the same party that profits when you don't. Forms, adjusters, weeks of waiting — all downstream of that one misalignment. The result is an *opaque and slow* system.

\$23.8B

MARKET SIZE

FOR DEFI YIELD

Real yield is *scarce*.

Returns are paid in vaporware governance tokens and rise and fall with the crypto cycle — not with anything that exists off-chain.

- **Vaporware emissions** — farm tokens, not cash flow.
- **Crypto-correlated** — TVL moves with BTC and ETH.
- **No off-chain premium** — nothing real to underwrite.

THE SOLUTION

Parametric insurance, built on *prediction-market* rails.

Travelers hedge against delays. Underwriters get paid when flights land on time. The contract settles automatically.

01

Settled automatically

Flight delayed? Payout in minutes. No forms, no adjusters.

02

Contract is the policy

Every rule lives on-chain — fully transparent. No fine print, no hidden clauses.

03

100% backed

Every policy pre-funded. Solvency is enforced by the smart contract.

04

ML-priced yield

An AI agent trained on 5 years of BTS data prices each route — minimizing risk for underwriters.

The oracle runs inside a *TEE*.

For a trust-minimized setup, the Oracle code that calls the APIs runs inside a **Trusted Execution Environment**. We use **Acurast** — a distributed TEE network powered by old phones.

Tamper-proof oracle code trust

Without a TEE, an oracle is only as honest as the server running it. Inside a TEE, the hardware itself attests the code is unmodified — nobody can forge a result.

Signing key never leaves the chip hardware

The Oracle's signing key is generated and stored inside the secure enclave. Not even the node operator can extract it.

Acurast — distributed TEE on old phones network

Retired Android phones with secure chips become trusted compute nodes. No data center, no single operator — redundant by default.

Publicly verifiable code hash audit

We publish the hash of the Oracle code running inside the TEE. Anyone can verify what's actually executing matches what we claim.

Classifier looks *backward*. Agent looks *forward*.

LAYER 1 · HISTORICAL BASELINE

Classifier trained on BTS data

Trained on 5 years of US flight on-time data.
Predicts delay probability per route.

Delta JFK→LAX, 9am Tue
→ 19% delay probability

LAYER 2 · TODAY'S SIGNAL

Live-search agent

History doesn't know about today's storm or war zone. The agent web-searches daily and returns a multiplier.

Storm forecast? → ×1.4 premium
War zone? → disable route

LAYER 3 · ON-CHAIN WRITE

RouteRepricer cron

Walks every whitelisted route daily. Applies the combined output via governance.

Significant drift → update
Unsafe → disable
Cleared → re-enable

BTS data → Classifier → Live-search agent → RouteRepricer cron → on-chain governance

WHY NOW

All three landed at *once*.

01

Prediction markets went mainstream

Polymarket and Kalshi normalized real-world on-chain settlement — both for consumers and regulators.

02

Stablecoins became real money

Sub-second settlement. Near-zero fees. Money you can finally move.

03

Trust-minimized AI is shippable

Fast chains and mature TEEs let AI agents run on-chain — decentralized, autonomous, no human in the loop.

ADDRESSABLE MARKET

Flights are the *wedge*.

The cleanest possible first feed. The same architecture serves every parametric insurance market that can be automated on-chain.

01 • THE WEDGE

Flight delay insurance
starts here

Binary outcome, same-day settled, public data, decades of training history.

02 • NEAR-TERM TAM

All parametric insurance
\$19B → \$35B

Weather, crop, shipping, event cancellation.
Same protocol — different data feed.

03 • LONG-TERM CEILING

Uninsured climate risk
\$2.9T

Cumulative uninsured catastrophe losses over the last 40 years.

CURRENT STATE

More than decks and *vibes*.

v3 of the protocol, live on four testnets. Built across multiple hackathons and the Stellar Foundation grant since February. Mainnet beta on Soroban in June.

01 · ITERATED

v3

Third iteration of architecture

Tested multiple TEEs and architectures across hackathons. Funded the latest rewrite with a Stellar Foundation grant.

02 · MULTI-CHAIN

4

Testnet deployments

Solana · Stellar Soroban · Base · Hedera. Same protocol, four runtimes.

03 · NEXT

June

Mainnet beta on Soroban (Stellar)

Whitelisted accounts, funded by the Stellar Foundation grant. Production-ready architecture, audit-ready contracts.

BUSINESS MODEL

Two ways the protocol *earns*.

01 • TAKE RATE

5%

Of every premium bought

Protocol takes 5% of all premium volume. Scales linearly with traveler activity.

02 • LP YIELD

Vault

Our capital on the underwriter side

We deploy our own capital as an underwriter on the protocol and earn yield from every insurance sold.

GO-TO-MARKET

Three *concentric rings*.

RING 1 · CRYPTO-NATIVE

now → Q4 2026

Direct dapp & conference partnerships

Wallet Standard connect for crypto-native travelers. Partnerships with **EthDenver**, **EthCC**, **Permissionless** and others to cover flights for conference-goers.

RING 2 · CROSSOVER

Q1 2027

Chrome extension

"Add delay insurance" injected at the booking moment on Expedia, Kayak, Google Flights. Reuses the same on-chain protocol.

RING 3 · MAINSTREAM

after volume

Travel platform partnerships

Once we have volume and can offer competitive prices, partner directly with the big travel sites and OTAs as the embedded delay-insurance provider.

TEAM

Two senior engineers. Each can build *every layer*.

S

Saurav Dhar

FOUNDER · CHICO, CALIFORNIA

- ✓ 11 years of software engineering.
- ✓ 2 years of blockchain development across Solidity, Rust, and applied ZK.
- ✓ Founding engineer at a Boost VC startup that exited successfully; built the software from scratch.
- ✓ BS in Electrical Engineering, UT Dallas.
- ✓ MS in Electrical Engineering, Virginia Tech.
- ✓ Master's thesis on scientific-instrumentation calibration for CubeSats and nanosatellites.

J

Jonas

FOUNDING ENGINEER · VILNIUS, LITHUANIA

- ✓ 8 years of software engineering, ex-big-bank platform engineer.
- ✓ 2 years of blockchain development across Solidity, Rust, and Move.
- ✓ BS in Computer Science.
- ✓ Open-source contributor to OpenZeppelin's Rust Contracts library for Soroban.
- ✓ Helped standardize SEP-56, the vault primitive used across the Soroban ecosystem.

THE ASK

Raising *\$1.5M* seed.

24 months of runway — from audit and mainnet to first traction.

01 · TEAM

\$650k

Engineer + Growth Lead

Two new hires on top of the current team, fully loaded across 24 months.

02 · UNDERWRITER FUND

\$500k

Vault seed capital

Protocol-owned underwriter capital so day-one policies aren't capacity-gated.

03 · LEGAL & REGULATORY

\$200k

Insurance opinions

Parametric-insurance opinions and entity setup across US, EU, and Singapore.

04 · BUFFER

\$150k

Operating runway

24-month operating buffer for unforeseen costs and runway flexibility.

*"We're not asking you to fund vibes.
The protocol exists. The thesis is testable in 24 months."*
